MEASLES VACCINE DISTRIBUTION

A total of more than 20 million doses of live attenuated measles virus vaccine were distributed by manufacturers from licensure in March 1963 through October 1966 (Figure 1). This total represents 19,279,941 doses officially reported through September 1966 and an estimated 948,000 for October 1966.

For the last 12 months for which data are available (November 1965 through October 1966), 8,069,148 doses were distributed. This represents more than twice the amount of vaccine which would be required to immunize the nearly four million children born in the United States during the same 12-month period. During the comparable

months in 1964 and 1965, a total of 5,790,575 doses was distributed.

(Reported by the Childhood Viral Diseases Unit and the Statistics Section, Epidemiology Branch, CDC.)

LIVE MEASLES VIRUS VACCINE DISTRIBUTED IN UNITED STATES
1963-1966

**CURRENT TRENDS
MEASLES - 1966**

A total of 1,338 cases was reported for the week ending December 10, 1966, a decrease of 134 cases from the previous week. Seven states notified more than 50 cases each and together accounted for 54.9 percent of the total reported: Texas, Washington, Oregon, Mississippi, North Dakota, California, and Oklahoma. Through the 49th week the total number of cases for the 1966 calendar year is 199,168, which is 57,282 less than the 256,450 cases

reported for the comparable period in 1965.

The counties reporting "outbreaks" of measles through the 48th week (ending December 3) are shown in Table 1. Sixteen counties in eight states notified almost 30 percent of the United States total for that week.

(Reported by the Childhood Viral Diseases Unit, Epidemiology Branch, CDC.)

*Criteria for "outbreaks":

Pop. at least 1,000,000: 25 cases/week for 2 consecutive weeks.

Pop. 500,000-999,999: 20 cases/week for 2 consecutive weeks.

Pop. 100,000-499,999: 15 cases/week for 2 consecutive weeks.

Pop. less than 100,000: 10 cases/week for 2 consecutive weeks.

†Organized control measures undertaken according to reports received by MMWR.

EPIDEMIOLOGIC NOTES AND REPORTS - GASTROENTERITIS - Oregon

An outbreak of acute gastroenteritis occurred among 77 persons following a luncheon attended by 147 people on October 18, 1966, in Bend, Oregon. The illness was mild in severity, with only one person hospitalized because of dehydration. Chicken salad was suspected of being responsible for the outbreak; *Clostridium perfringens* was identified on culture.

Investigational interviews were obtained from 112 of the participants. Of these, 70 percent became ill. The symptoms among 73 patients are shown in Table 2; diarrhea and cramps predominated while vomiting was infrequent. The duration of illness ranged from one to 36 hours with a median of 10 hours. The epidemic curve revealed a range of incubation period from 6 to 24 hours with a median of 15 hours.

Attack rates according to history of foods eaten failed to incriminate any single food (Table 3). The chicken salad was eaten by all but two of those interviewed. These two who did not eat the salad did not become ill, which

Lettuce	14	13	27	51.7	14	6	20	70.0

suggests that the salad may have been the vehicle of infection. No illness was reported among other family members of the group questioned.

The chicken salad was prepared from canned chicken which was cooked, diced, and freeze-dried prior to canning. The product is not refrigerated until after it is rehydrated. At 2:00 p.m. on October 17, two-thirds of a cup of powdered chicken broth mix was added to 24 quarts of hot water which was stirred and then cooled for 10 minutes. Twenty-four cans of chicken were opened and rehydrated when added to the broth. The mixture was allowed to stand for 15 minutes for further cooling before the broth was drained.

At 5:50 p.m., the chicken was divided into two large batches and put into two bowls that were placed in a walk-in refrigerator which has a temperature between 35° and 40°F. Hard-boiled eggs were prepared and refrigerated that same day.

On October 18 at approximately 11:00 a.m., sweet pickles, fresh diced celery and cucumbers, diced hard-boiled eggs, mayonnaise, and lemon juice were mixed in with the rehydrated chicken in a large stainless steel bowl. Individual portions of the chicken salad were then placed on lettuce leaves using an ice cream scoop. The salad

GASTROENTERITIS - Oregon

(Continued from page 427)

was not refrigerated again before the 1:00 p.m. luncheon.

The chicken salad was found to be contaminated with *Clostridium perfringens* with anaerobic colony counts of 60,000/gram and 11,400/gram on two occasions. The organism has not yet been typed with Hobbs' sera. The lot number of the cans used to make the chicken salad could not be determined. However, the two remaining sealed cans of dehydrated chicken which had different lot numbers but were taken from the same shipment were cultured and found to be negative. Other foods served were cultured and also were negative.

On Saturday, October 15, a similar luncheon was served to a large group of people in Oregon. The chicken salad was prepared in the same manner but on the same day as the luncheon. Salad not eaten at lunch was served to a small group for dinner. There was no leftover chicken salad. No reported illness followed the Saturday luncheon or dinner.

(Reported by Dr. Edward L. Goldblatt, State Epidemiologist, Oregon State Board of Health; and Mr. Jon F. Thompson, Senior Sanitarian, Mr. Ron Anderson, Sanitarian, Dr. C. J. Rademacher, Acting County Health Officer, and several public health nurses, all of the Tri-County Health Department, Portland, Oregon; and an EIS Officer.)

Editorial Note:

In the first well-documented report of *Clostridium perfringens* (*C. welchii*) food poisoning in the United States, which was published in 1945, chicken was incriminated as the source of the contamination.¹ Since then, poultry frequently has been implicated on epidemiological grounds as the cause of outbreaks. In addition, *C. perfringens* has been isolated from poultry in different food surveys.^{2,3}

This report of the Oregon luncheon offers presumptive evidence of *C. perfringens* food poisoning. Supporting this are the classical food preparation history, the typical epidemic curve, clinical features, incubation period, and the isolation of *C. perfringens* from the chicken salad despite the relatively low anaerobic colony counts. The food histories indicated the chicken salad as a possible vehicle of infection although too small a number of people did not eat the salad to provide definitive evidence. Considering the ubiquity of this organism, it would have been desirable to obtain *C. perfringens* isolates not only from stools of the patients, and test them for specific serotypes.

THE MORBIDITY AND MORTALITY WEEKLY REPORT, WITH A CIRCULATION OF 15,600, IS PUBLISHED AT THE COMMUNICABLE DISEASE CENTER, ATLANTA, GEORGIA

CHIEF, COMMUNICABLE DISEASE CENTER
CHIEF, EPIDEMIOLOGY BRANCH
ACTING CHIEF, STATISTICS SECTION

DAVID J. SENCER, M.D.
A.D. LANGMUIR, M.D.
IDA L. SHERMAN, M.S.

IN ADDITION TO THE ESTABLISHED PROCEDURES FOR REPORTING MORBIDITY AND MORTALITY, THE COMMUNICABLE DISEASE CENTER WELCOMES ACCOUNTS OF INTERESTING OUTBREAKS OR CASE INVESTIGATIONS WHICH ARE OF CURRENT INTEREST TO HEALTH OFFICIALS AND WHICH ARE DIRECTLY RELATED TO THE CONTROL OF COMMUNICABLE DISEASES. SUCH COMMUNICATIONS SHOULD BE ADDRESSED TO:

THE EDITOR
MORBIDITY AND MORTALITY WEEKLY REPORT
COMMUNICABLE DISEASE CENTER
ATLANTA, GEORGIA 30333

NOTE: THE DATA IN THIS REPORT ARE PROVISIONAL AND ARE BASED ON WEEKLY TELEGRAMS TO THE CDC BY THE INDIVIDUAL STATE HEALTH DEPARTMENTS. THE REPORTING WEEK CONCLUDES ON SATURDAY; COMPILED DATA ON A NATIONAL BASIS ARE RELEASED ON THE SUCCEEDING FRIDAY.
